# State Pooling and Belief Polarization

## Puzzle

- ▶ Society today is more polarized (McCarty et al. 2006)
- ▶ Information is more easily accessible (lower cost)
- ▶ If a “true state” exists, beliefs should converge, right?
- ▶ Not necessarily true if information collection is endogenous

## Summary

- ▶ **Setup:** the action space is smaller than the state space (e.g. 2 actions safe/risky and 3 states), the agents collect evidence before choosing an action
- ▶ **State pooling:** agents avoid redundant information and “pool together” states associated with the same action
- ▶ **Belief polarization:** posterior beliefs are more distant (extreme) than prior beliefs

# State Pooling and Belief Polarization

## Puzzle

- ▶ Society today is more polarized (McCarty et al. 2006)
- ▶ Information is more easily accessible (lower cost)

# MOTIVATING EXAMPLE

# Motivating Example

## Setting

- ▶ Alice and Bob face a choice: go to the Theater or stay Home
  - ▶ Theater: uncertainty about the quality of the movie [state  $s$ ]
  - ▶ Home: “safe” choice [status quo]

	Theater	Home	
$s$	$v_i^T(s)$	$v_A^H(s)$	$v_B^H(s)$
bad	0	0.45	0.55
medium	0.5	0.45	0.55
good	1	0.45	0.55

- ▶ Assume uniform prior  $p_s = \frac{1}{3}$  and risk neutrality

# Motivating Example

## Scenario 1

- ▶ Alice and Bob have the same beliefs over  $s$  and  $EV(\text{Theater})$ 
  - ▶  $EV(\text{Theater}) = 0.5$
- ▶ Alice and Bob make different choices
  - ▶ A chooses Theater as  $0.5 = EV(\text{Theater}) > EV(\text{Home}) = 0.45$
  - ▶ B chooses Home as  $0.5 = EV(\text{Theater}) < EV(\text{Home}) = 0.55$

	Theater	Home	
$s$	$v_i^T(s)$	$v_A^H(s)$	$v_B^H(s)$
bad	0	0.45	0.55
medium	0.5	0.45	0.55
good	1	0.45	0.55

# Motivating Example

## Scenario 2

- ▶ Same problem as before, but now A and B can collect “some” information about the movie quality
- ▶ Note that we have 2 actions (T/H) and 3 states (b/m/g)
  - ▶ For Alice it is *sufficient* to know if the movie is b or (m/g)

	Theater	Home	
$s$	$v_i^T(s)$	$v_A^H(s)$	$v_B^H(s)$
bad	0	0.45	0.55
medium	0.5	0.45	0.55
good	1	0.45	0.55

# Motivating Example

## Scenario 2

- ▶ Same problem as before, but now A and B can collect “some” information about the movie quality
- ▶ Note that we have 2 actions (T/H) and 3 states (b/m/g)
  - ▶ For Bob it is *sufficient* to know if the movie is (b/m) or g

	Theater	Home	
$s$	$v_i^T(s)$	$v_A^H(s)$	$v_B^H(s)$
bad	0	0.45	0.55
medium	0.5	0.45	0.55
good	1	0.45	0.55

# Motivating Example

## Scenario 2

- ▶ If the movie is good (bad) they agree about the action Theater (Home)
- ▶ But they do not agree about the expected quality of the movie
  - ▶ Good movie:  $EV_A(T|g) = 0.75 < EV_B(T|g) = 1$
  - ▶ Bad movie:  $EV_A(T|b) = 0 < EV_B(T|b) = 0.25$
- ▶ If the movie is medium they still disagree about the action
- ▶ But they also disagree about the expected quality of the movie
  - ▶ Alice chooses Theater:  $EV_A(T|m) = 0.75$
  - ▶ Bob chooses Home:  $EV_B(T|m) = 0.25$

# Motivating Example

## Scenario 2

- ▶ If the movie is good (bad) they agree about the action Theater (Home)
- ▶ But they do not agree about the expected quality of the movie
  - ▶ Good movie:  $EV_A(T|g) = 0.75 < EV_B(T|g) = 1$
  - ▶ Bad movie:  $EV_A(T|b) = 0 < EV_B(T|b) = 0.25$
- ▶ If the movie is medium they still disagree about the action
- ▶ But they also disagree about the expected quality of the movie
  - ▶ Alice chooses Theater:  $EV_A(T|m) = 0.75$
  - ▶ Bob chooses Home:  $EV_B(T|m) = 0.25$

# Motivating Example

## Summary

- ▶ Alice and Bob have the same prior beliefs
- ▶ But they have different preferences (outside option)
- ▶ The introduction of **endogenous information collection** created disagreement about movie quality
- ▶ Stock/bond investment, Referendum vote (e.g. Brexit), etc.

## Definitions (again)

- ▶ **State pooling**: agents avoid redundant information and “pool together” states associated with the same action
- ▶ **Belief polarization**: posterior beliefs are more distant (extreme) than prior beliefs

# Motivating Example

## Summary

- ▶ Alice and Bob have the same prior beliefs

# RESEARCH QUESTION

# Research Question

## Can we observe belief polarization and identify its drivers in a lab experiment?

This question can be divided into three smaller ones:

1. **How do agents evaluate and choose information sources?**

We replicate well-known results (compression of WTP wrt optimal value, preference for certainty)

2. **Do we observe (preference for) state pooling?**

Yes, we report new evidence of preference for “state pooling” and “extreme” information

3. **Do we observe belief polarization (by changing Safe)?**

Yes, a change in the safe option generates “information switch” as predicted, and creates belief polarization

# Research Question

## Can we observe belief polarization and identify its drivers in a lab experiment?

This question can be divided into three smaller ones:

1. **How do agents evaluate and choose information sources?**

We replicate well-known results (compression of WTP wrt optimal value, preference for certainty)

2. **Do we observe (preference for) state pooling?**

Yes, we report new evidence of preference for “state pooling” and “extreme” information

3. **Do we observe belief polarization (by changing Safe)?**

Yes, a change in the safe option generates “information switch” as predicted, and creates belief polarization

# LABORATORY EXPERIMENT

# Laboratory Experiment

- ▶ **How do agents evaluate and choose information sources?**
- ▶ **Do we observe (preference for) state pooling?**
- ▶ **Do we observe belief polarization (by changing Safe)?**
- ▶ Stage 1: choose or “hire” an advisor (experiment)
- ▶ Observe signal realization
- ▶ Stage 2: select an action [risky/safe]
- ▶ We collect separately
  - ▶ Choices over sources of information (advisors)
  - ▶ Action (conditional on realized signals)
  - ▶ Elicited beliefs (signal probability and posterior)
  - ▶ Willingness to pay for signal structures

# Laboratory Experiment

- ▶ **How do agents evaluate and choose information sources?**
- ▶ **Do we observe (preference for) state pooling?**
- ▶ **Do we observe belief polarization (by changing Safe)?**
- ▶ Stage 1: choose or “hire” an advisor (experiment)
- ▶ Observe signal realization
- ▶ Stage 2: select an action [risky/safe]
- ▶ We collect separately
  - ▶ Choices over sources of information (advisors)
  - ▶ Action (conditional on realized signals)
  - ▶ Elicited beliefs (signal probability and posterior)
  - ▶ Willingness to pay for signal structures

# Laboratory Experiment

- ▶ Experiment conducted at Columbia in August-September 2019
- ▶ 85 participants (undergraduate and graduate students)
- ▶ Average time 80 minutes, Average payment  $\sim$ \$25
  - ▶ Show-up fee (\$10)
  - ▶ Main experiment, 4 parts (probability points, \$15 prize)
  - ▶ Risk attitude (Holt-Laury, \$0.10-\$4.00)
  - ▶ Intelligence (Raven's Progressive Matrices, 5 x \$0.50)
  - ▶ Unrewarded questionnaire (strategy, LOT-R, demographics)

# PRELIMINARY RESULTS

## Task 2 - How did we design the pairs of advisor?

# Most of participants “switch” advisor optimally

# Accuracy depends on the stakes

# Simple Advisors: Certainty vs Certainty

- ▶ Each advisor “pools” two states out of three
- ▶ These trials are easy to interpret
- ▶ Participants switch in the red/blue choice...
- ▶ ...but they switch only when it is valuable to do so

# Certainty vs Uncertainty

# Aggregate Valuation of Advisors - Logit Regression

## Elicited Beliefs - Card color

## Elicited Beliefs - Ball color

# Beliefs Polarization - Predictions

# Beliefs Polarization - Predictions

# Beliefs Polarization - Predictions

# Beliefs Polarization - Predictions

# Beliefs Polarization - Predictions

# Beliefs Polarization - Predictions

# Beliefs Polarization - Predictions

# Beliefs Polarization - Data

# Beliefs Polarization - Counterfactual

# Beliefs Polarization - Predictions

# Compression in the WTP for Advisors in Task 1

# Questionnaire - Strategies

## State Pooling

- ▶ If low ball in transparent box, pick advisor most likely to reveal blue or yellow, vice versa
- ▶ I chose based on whichever advisor's information could tell me more about the single ball I either really did or did not want to pick

## Other strategies

- ▶ CERTAINTY - I would choose the advisor which had the same color of cards for each color ball
- ▶ BLUE - To make sure if it is blue
- ▶ RED - I chose the advisor of the ball I didn't want to get on the opaque box, and if that was the color that was on the box, I went with the transparent box
- ▶ TALKATIVE - Probability

# Summary

- ▶ **Motivation:** Empirical evidence of belief polarization (BP)
- ▶ **Setup:** 3 states and 2 actions (safe/risky)
- ▶ Endogenous information acquisition generates BP
- ▶ **Lab experiment:**
  - ▶ A change in the safe option generates “advisor switches” as predicted...
  - ▶ ... and creates (mitigated) belief polarization.
  - ▶ We replicate well-known results (compression, preference for certainty) in a new setup with 3 states...
  - ▶ ... and we report novel evidence: preference for “state pooling” and “extreme states” advisors.

## Appendix C - Confounding Factors

▶ Appendix C

# APPENDIX A - THE MODEL

# Full Model (Matveenko and Novak)

- ▶ DM is rationally inattentive (Sims, 2003, 2006)
  - ▶ Information costly - Shannon cost
  - ▶  $\lambda$  - marginal cost of information
  - ▶  $\kappa(P, G)$  - **expected reduction in entropy**
  - ▶  $G(v)$  prior distribution
  - ▶  $P(i|v)$  probability of choosing action  $i$  conditional on  $v$
- ▶ Main result: possible "wrong direction" updating of beliefs dependent on respective position of prior beliefs and safe option. It leads to polarization (more extreme posterior beliefs).

# Agent's problem

Denote:  $\mathbf{v} = (v_1, \dots, v_n)$ ,  $G(\mathbf{v})$  - prior joint distribution

Find an information strategy maximizing:

$$\max_{P(i|\mathbf{v})} \left\{ \sum_{i=1}^2 \int_{\mathbf{v}} v_i P(i|\mathbf{v}) G(d\mathbf{v}) - \lambda \kappa(P, G) \right\},$$

where

$$\kappa(P, G) = - \sum_{i=1}^2 P_i^0 \ln P_i^0 + \int_{\mathbf{v}} \left( \sum_{i=1}^2 P(i|\mathbf{v}) \ln P(i|\mathbf{v}) \right) G(d\mathbf{v}).$$

$P(i|\mathbf{v})$  is the conditional on the realized value of  $\mathbf{v}$ , the probability of choosing option  $i$  and

$$P_i^0 = \int_{\mathbf{v}} P(i|\mathbf{v}) G(d\mathbf{v}), \quad i = 1, 2$$

where  $P_i^0$  is the unconditional probability of option  $i$  to be chosen.

## Lemma 1 (Matějka, McKay, 2015)

Conditional on the realized state of the world  $s^*$  probability of choosing risky option is

$$P(\text{picking risky} | \text{state is } s^*) = \frac{P_1^0 e^{\frac{v_s^*}{\lambda}}}{P_1^0 e^{\frac{v_s^*}{\lambda}} + (1 - P_1^0) e^{\frac{R}{\lambda}}}$$

of choosing safe option is:

$$P(\text{picking safe} | \text{state is } s^*) = \frac{(1 - P_1^0) e^{\frac{R}{\lambda}}}{P_1^0 e^{\frac{v_s^*}{\lambda}} + (1 - P_1^0) e^{\frac{R}{\lambda}}}$$

here  $P_1^0$  is unconditional probability of choosing risky option.

# Beliefs

- ▶ Agent's prior expected value of the risky option is:

$$\mathbb{E}v = \sum_{s=1}^n v_s g_s$$

we **fix the state** of the nature: it is  $s^*$

- ▶ Observer sees agent's updated belief about the average of  $v$ :

$$\begin{aligned}\mathbb{E}_i[\mathbb{E}(v|i)|s^*] &= P(i = 1|s^*)\mathbb{E}(v|\text{picking option 1})+ \\ &\quad + (1 - P(i = 1|s^*))\mathbb{E}(v|\text{picking option 2})\end{aligned}$$

where for option  $i \in \{1, 2\}$

$$\mathbb{E}(v|\text{picking option } i) = \sum_{j=1}^n v_j P(\text{state is } j|\text{picking option } i)$$

# Beliefs

## Theorem

Expected posterior value of the risky option for a rationally inattentive decision maker is

$$\mathbb{E}_i[\mathbb{E}(v|i)|s^*] = \sum_{i=1}^n v_i g_i \frac{\alpha_{s^*} e^{\frac{v_i}{\lambda}} + (1 - \alpha_{s^*}) e^{\frac{R}{\lambda}}}{P_1^0 e^{\frac{v_i}{\lambda}} + (1 - P_1^0) e^{\frac{R}{\lambda}}} \quad (1)$$

where

$$\alpha_{s^*} = \frac{P_1^0 e^{\frac{v_{s^*}}{\lambda}}}{P_1^0 e^{\frac{v_{s^*}}{\lambda}} + (1 - P_1^0) e^{\frac{R}{\lambda}}}$$

# Updating of beliefs

We are interested in

$$\Delta = \mathbb{E}_i[\mathbb{E}(v|i)|s^*] - \mathbb{E}v$$

## Theorem

The sign of  $\Delta$  is the same as the sign of  $(v_{s^*} - R)$ .

## Proof.

Straightforward and we use:

## Lemma 2

Relations  $\alpha_{s^*} \geq P_1^0$  under  $P_1^0 > 0$  are equivalent to  $v_{s^*} \geq R$

## Example 3 states, 2 actions

- ▶ 3 possible states of the world - indexed by  $s$
- ▶ 2 options/actions - indexed by  $a$ 
  - ▶ Option 1 - Risky with values:  $v_1 < v_2 < v_3$
  - ▶ Option 2 - Safe option with value  $R$  in all states
- ▶ Prior belief about the states:  $g_1, g_2, g_3$
- ▶ Marginal cost of information:  $\lambda$

**Assumption 1:** to rule out uninteresting cases

$$v_1 < R < v_3$$

# Updating in "wrong" direction

We are interested when the conditional expectation moves in the  
**"wrong" direction**

**Example** for  $s^* = 1$  the expectation "should" go down, so the agent is biased when

$$\mathbb{E}_a[\mathbb{E}(v|a)|s^*] > \mathbb{E}v > 0$$

# Updating in "wrong" direction

Let's denote  $\Delta = \mathbb{E}_a[\mathbb{E}(v|a)|s^*] - \mathbb{E}v$ .

If

$$(\mathbb{E}v - v_{s^*}) \cdot \Delta > 0$$

then the agent is updating belief in the wrong direction

# Result

# APPENDIX B - LITERATURE

# Information and Belief Polarization

- ▶ Polarization is an ubiquitous phenomenon
- ▶ Mixed evidence of how information contributes to polarization
  - ▶ Politicians and voters more polarized despite increased availability of information  
McCarty, Poole and Rosenthal (2006)
  - ▶ Greater Internet use is not associated with faster growth in political polarization among US demographic groups  
Boxell, Gentzkow and Shapiro (2017)

▶ Back to Literature slides

# Multiple Explanations for Polarization

## 1. Confirmation bias

- ▶ Misreading ambiguous signals: Rabin, Schrag (1999); Fryer, Harms, Jackson (2017)
- ▶ Limited memory: Wilson (2014)
- ▶ Experiments: Lord, Ross, Lepper (1979)

## 2. Overconfidence and correlation neglect

- ▶ Ortoleva and Snowberg (2015)

## 3. Positive test strategy

- ▶ Klayman and Ha (1987), Nickerson (1998)

Results mostly based on **exogeneous information** and/or exogeneously imposed biases.

▶ [Back to Literature slides](#)

# Confirmation Bias and Rational Inattention

## 1. Su (2014)

- ▶ Gaussian signal + quadratic loss function
- ▶ Attention proportional to observation window
- ▶ Results: conformism in learning

## 2. Nimark and Sundaresan (2018)

- ▶ Mainly focus on polarization persistence
- ▶ Agent pays more attention to the states which are more likely

## 3. Dixit and Weibull (2007) - not RI

- ▶ Learning about policy in place (signal bimodal)
- ▶ Agents agree on loss function, disagree on probabilities of states
- ▶ Status quo vs. new reform - Divergence of opinions

# Experimental Literature

## 1. Ambuehl and Li (2018)

- ▶ Systematic analysis of belief updating and demand for information
- ▶ Compression effect: subjective valuation of useful information underreacts to increased informativeness
- ▶ Biases mainly due to non-standard belief updating rather than risk preferences

## 2. Charness, Oprea, and Yuksel (2018)

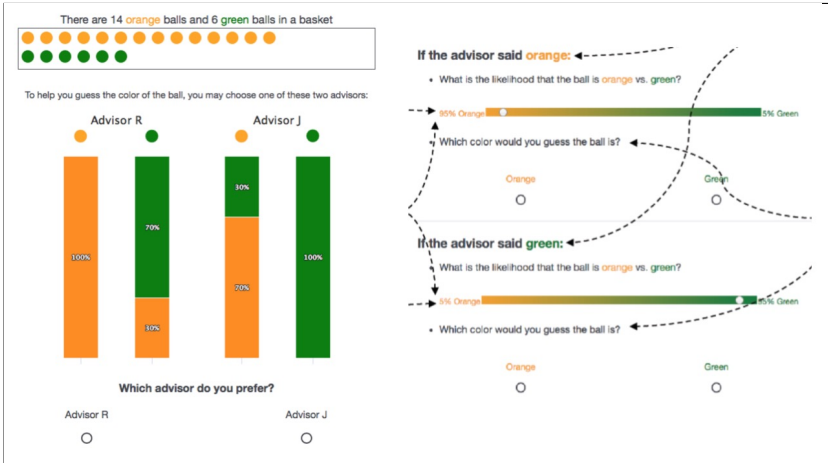

- ▶ Study how people choose between biased information sources
- ▶ Evidence of confirmation-seeking rule
- ▶ Mistakes are driven by errors in reasoning about informativeness

# Ambuehl and Li (2018)

- ▶ Prediction game
- ▶ **Information valuation task**
- ▶ Belief updating task
- ▶ Eliciting signal probabilities
- ▶ Gradual information task

## Charness, Oprea, and Yuksel (2018)

# APPENDIX C

## CONFOUNDING FACTORS

# Who killed BP in the lab? A list of usual suspects

- ▶ Risk attitude
- ▶ Noise/randomness
- ▶ Inertia
- ▶ Status quo effect
- ▶ Wrong updating (base-rate neglect, conservatism)
- ▶ Updating strength affected by irrelevant variables
- ▶ Confirmatory strategy (positive test)
- ▶ Preference over non-instrumental information
- ▶ Signal avoidance (ostrich effect)
- ▶ Biased information cost/value function (compression)
